LACE1 is encoded by a gene mapping to human chromosome 6. Making up nearly 6 $\%$ of the
human genome, chromosome 6 contains around 1,200 genes within 170 million base pairs of
sequence. Deletion of a portion of the q arm of chromosome 6 is associated with early onset
intestinal cancer suggesting the presence of a cancer susceptibility locus. Porphyria cutanea
tarda is associated with chromosome 6 through the HFE gene which, when mutated,
predisposes an individual to developing this porphyria. Notably, the PARK2 gene, which is
associated with Parkinson's disease, and the genes encoding the major histocompatiblity
complex proteins, which are key molecular components of the immune system and determine
predisposition to rheumatic diseases, are also located on chromosome 6. Stickler syndrome,
21-hydroxylase deficiency and maple syrup urine disease are also associated with genes on
chromosome 6. A bipolar disorder susceptibility locus has been identified on the q arm of
chromosome 6.
