|--|
| Background: Glycophorins A, B and C are sialoglycoproteins of the human erythrocyte |
| membrane, which bear the antigenic determinants for the MN, Ss and Gerbich blood groups, |
| respectively. Glycophorins span the membrane once and present their amino-terminal end to |
| the extracellular surface of the human erythrocyte. The genetic array of expressed glycophorin |
| surface antigens on erythrocytes defines the blood group phenotype of the individual. The |
| human Glycophorin A gene maps to chromosome 4q31.21, contains seven exons which are |
| 97 % homologous to Glycophorin B, and encodes a 150 amino acid protein. The human |
| Glycophorin B gene maps to chromosome 4q31.21 and encodes a 91 amino acid protein. The |
| human Glycophorin C gene maps to chromosome 2q14.3 and contains four exons. Glycophorin |
| C transcript can generate two protein isoforms. Isoform 1 includes all 4 exons and encodes the |
| full length 128 amino acid protein. Isoform 2 is missing exon 2 and encodes a 109 amino acid |
| protein, which specifies the Yus subtype of the Gerbich phenotype. |
