	Background: EVC is an autosomal skeletal dysplasia caused by mutations in the EVC and EVC2
	genes. Found in developing ribs, heart, kidney and lung, the EVC gene is responsible for normal
	development of the face, limbs, teeth and nails. The protein expressed by the EVC gene is an
	intracellular component of the hedgehog signal pathway that contains a leucine zipper and
	transmembrane domain. Defects in the EVC gene can lead to short-limb dwarfism, ectodermal
	dysplasia and cardiac anomalies such as irregular atrioventricular septum development.
	Additionally, the EVC gene has been implicated in Weyers acrodental dysostosis, an autosomal
	dominant disease characterized by facial abnormalities and limb defects.
