	Background: Synaptotagmins are a large family of synaptic vesicle type III integral membrane	
	proteins that function as regulators of both exocytosis and endocytosis and are involved in	
	neurotransmitter secretion from small secretory vesicles. Synaptotagmin XI, also known as	
	SYT11 (Synaptotagmin-11), is a 431 amino acid protein that localizes to the membrane and is expressed ubiquitously with highest expression in brain and lung. Like other Synaptotagmin proteins, Synaptotagmin XI is involved in the calcium-dependent exocytosis of secretory	
	vesicles and is thought to act as a calcium sensor during vesicular trafficking. Synaptotagmin	
	XI contains two C2 domains through which it can bind either three calcium ions or the zinc-	
	finger protein Parkin (a juvenile Parkinson?s disease gene product), the latter of which causes	
	the polyubiquitination and subsequent degradation of Synaptotagmin XI by the proteasome	
	complex. Defects in the gene encoding Synaptotagmin XI are implicated in a number of	
	neurological disorders, including schizophrenia and Parkinson?s disease.
