	Background: Voltage-gated K+ channels in the plasma membrane control the repolarization and
	the frequency of action potentials in neurons, muscles, and other excitable cells. The KV gene
	family encodes more than 30 genes that comprise the subunits of the K+ channels, and they
	vary in their gating and permeation properties, subcellular distribution, and expression patterns.
	Functional KV channels assemble as tetramers consisting of pore-forming a-subunits (KV),
	which include the KV1, KV2, KV3, and KV4 proteins, and accessory or KV-subunits that modify
	the gating properties of the coexpressed KV subunits. Differences exist in the patterns of
	trafficking, biosynthetic processing, and surface expression of the major KV1 subunits (KV1.1,
	KV1.2, and KV1.4) expressed in rat and human brain, suggesting that the individual protein
	subunits are highly regulated to control for the assembly and formation of functional neuronal
	channels. KV beta.2 can also be designated KCNAB2, KKv beta2.1 or AKR6A5.
