	Background: Members of the bactericidal/permeability-increasing protein family have
	antimicrobial properties and bind lipophilic substances, therefore targeting gram-negative
	bacteria. The bactericidal permeability increasing protein (BPI) is an antibacterial and
	endotoxin-neutralizing molecule that is abundant in the granules of polymorphonuclear
	leukocytes (neutrophil granules). Sharing structural and sequence homologies with BPI, BPIL2
	(Bactericidal/permeability-increasing protein-like 2) is a 507 amino acid secreted protein that
	contains the family?s common conserved feature of two cysteine residues that are critical for
	protein function. While BPIL2 is expressed in the basal layer of inflamed epidermis from
	psoriasis patients, it is not detected in normal skin.
