| Background: C14orf106 is required for recruitment of CENPA to centromeres and normal           |
|--|
| chromosome segregation during mitosis. It interacts with SP1. There are two                    |
| isoforms.Chromosome 14 contains about 700 genes and 106 million base pairs and makes up        |
| about 3.5 % of human cellular DNA. Chromosome 14 encodes the presinilin 1 (PSEN1) gene,        |
| which is one of the three key genes associated with the development of Alzheimer's disease.    |
| The SERPINA1 gene is located on chromosome 14 and when defective leads to the genetic          |
| disorder ?-antitrypsin deficiency. This disorder is characterized by severe lung complications |
| and liver dysfunction. Notably, the immunoglobulin heavy chain locus is found on chromosome    |
| 14 and has been identified as a fusion with the chromosome 19 encoded protein BCL3 in the      |
| (14,19) translocations found in a variety of B cell malignancies. The C14orf106 gene product   |
| has been provisionally designated C14orf106 pending further characterization.                  |
