| | Background: HECA, also known as headcase homolog, HDC, HDCL or HHDC, is a 543 amino |
|---------------------|--|
| | acid mammalian homolog of the Drosophila headcase protein, a highly basic, cytplasmic |
| | peptide that plays a role in mitotic re-entry during adult morphogenesis. Expressed in a variety |
| | of tissues with highest expression in thymus, spleen and heart, HECA is thought to play a role in |
| | the development of epithelial tube networks in lung tissue and may also be involved in the |
| | pathogenesis of lung cancer. The gene encoding HECA maps to human chromosome 6, which |
| | contains 170 million base pairs and comprises nearly 6 % of the human genome. Deletion of a |
| | portion of the q arm of chromosome 6 is associated with early onset intestinal cancer, |
| | suggesting the presence of a cancer susceptibility locus. Additionally, Porphyria cutanea tarda, |
| | Parkinson's disease, Stickler syndrome and a susceptibility to bipolar disorder are all associated |
| | with genes that map to chromosome 6. |
