	Background: The formation of the spliceosome includes the assembly of Sm proteins in an
	ordered manner onto snRNAs. This process is mediated by the survival of motor neuron (SMN)
	protein, and is enhanced by modification of specific arginine residues in the Sm proteins to
	symmetrical dimethylarginines (sDMAs). sDMA modification of Sm proteins is catalyzed by the
	methylosome, a complex comprised of the type II methyltransferase PRMT5 (also designated
	Jak-binding protein 1, JBP1), pICIn, and two novel factors. PRMT5 binds the Sm proteins via
	their arginine- and glycine-rich (RG) domains, while pICIn binds the Sm domains. pICIn also acts
	as an inhibitor of SnRNP assembly by preventing specific interactions between Sm proteins
	required for the formation of the Sm core. pICIn is a highly conserved, ubiquitously expressed
	protein that localizes primarily to the cytoplasm, and may play a role as a swelling-activated
	anion channel or a channel regulator in addition to its function in the methylosome. The gene
	encoding human pICIn maps to chromosome 11q14.1.
