	Background: The endoplasmic reticulum exerts a quality control over newly synthesized	
	proteins and a variety of components have been implicated in the specific recognition of	
	aberrant or misfolded polypeptides. Signal peptide peptidase (SPP) catalyzes intramembrane	
	proteolysis of some signal peptides after they have been cleaved from a preprotein, resulting in	
	the release of the fragment from the ER membrane into the cytoplasm. SPP is required to	
	generate lymphocyte cell surface (HLA-E) epitopes derived from MHC class I signal peptides,	
	and may play a role in graft rejection. It also may be necessary for the removal of the signal	
	peptide that remains attached to the hepatitis C virus core protein after the initial proteolytic	
	processing of the polyprotein.
