	Background: The regulators of G protein signaling (RGS) proteins inhibit heterotrimeric G
	protein signaling. RGS proteins work by functioning as GTPase-activators (which increase the
	GTPase activity of G protein a-subunits) thereby driving G proteins into their inactive GDP-
	bound form. RGS21 (regulator of G-protein signaling 21) is a 152 amino acid protein that is
	ubiquitously expressed and contains one RGS domain. The gene encoding RGS21 maps to
	human chromosome 1q31.2 and mouse chromosome 1 F. Human chromosome 1 spans 260
	million base pairs, contains over 3,000 genes, comprises nearly 8 % of the human genome and
	houses a large number of disease-associated genes, including those that are involved in
	familial adenomatous polyposis, Stickler syndrome, Parkinson?s disease, Gaucher disease,
	schizophrenia and Usher syndrome.
