	Background: Zinc-finger proteins contain DNA-binding domains and have a wide variety of
	functions, most of which encompass some form of transcriptional activation or repression. The
	majority of zinc-finger proteins contain a Kr_ppel-type DNA binding domain and a KRAB
	domain, which is thought to interact with KAP1, thereby recruiting histone modifying proteins.
	As a member of the krueppel C2H2-type zinc-finger protein family, ZNF532 is a 1301 amino
	acid nuclear protein that contains twelve C2H2-type zinc fingers. The gene encoding ZNF532
	maps to human chromosome 18, which houses over 300 protein-coding genes and contains
	nearly 76 million bases, representing about 2.5 % of total DNA in cells. There are a variety of
	diseases associated with defects in chromosome 18-localized genes, some of which include
	Niemann-Pick disease, hereditary hemorrhagic telangiectasia, erythropoietic protoporphyria
	and follicular lymphomas.
