|---------------------|--|
| | Background: HEATR3 is a 680 amino acid protein existing as three alternatively spliced |
| | isoforms and containing two HEAT (Huntingtin, elongation factor 3 (EF3), protein phosphatase |
| | 2A (PP2A) and the yeast PI3-kinase Tor1) repeats. HEAT repeats form rod-like helical structures |
| | that are involved in intracellular transport. HEATR3 is encoded by a gene located on human |
| | chromosome 16, which encodes over 900 genes and comprises nearly 3 $\%$ of the human |
| | genome. The GAN gene is located on chromosome 16 and, with mutation, may lead to giant |
| | axonal neuropathy, a nervous system disorder characterized by increasing malfunction with |
| | growth. The rare disorder Rubinstein-Taybi syndrome is also associated with chromosome 16, |
| | as is Crohn's disease, a gastrointestinal inflammatory condition. |
