## **Target Details**

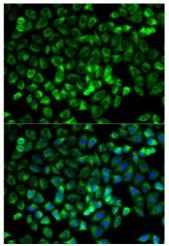

Target:	TPSAB1	
Alternative Name:	TPSAB1 (TPSAB1 Products)	
Background:	Tryptases comprise a family of trypsin-like serine proteases, the peptidase family S1. Tryptases	
	are enzymatically active only as heparin-stabilized tetramers, and they are resistant to all known	
	endogenous proteinase inhibitors. Several tryptase genes are clustered on chromosome	
	16p13.3. These genes are characterized by several distinct features. They have a highly	
	conserved 3' UTR and contain tandem repeat sequences at the 5' flank and 3' UTR which are	
	thought to play a role in regulation of the mRNA stability. These genes have an intron	
	immediately upstream of the initiator Met codon, which separates the site of transcription	
	initiation from protein coding sequence. This feature is characteristic of tryptases but is	
	unusual in other genes. The alleles of this gene exhibit an unusual amount of sequence	
	variation, such that the alleles were once thought to represent two separate genes, alpha and	
	beta 1. Beta tryptases appear to be the main isoenzymes expressed in mast cells, whereas in	
	basophils, alpha tryptases predominate. Tryptases have been implicated as mediators in the	
	pathogenesis of asthma and other allergic and inflammatory
