	Background: Chromosome 1 is the largest human chromosome spanning about 260 million	
	base pairs and making up 8 % of the human genome. There are about 3,000 genes on	
	chromosome 1, and considering the great number of genes there are also a large number of	
	diseases associated with chromosome 1. Notably, the rare aging disease Hutchinson-Gilford	
	progeria is associated with the LMNA gene which encodes lamin A. When defective, the LMNA	
	gene product can build up in the nucleus and cause characteristic nuclear blebs. The	
	mechanism of rapidly enhanced aging is unclear and is a topic of continuing exploration. The MUTYH gene is located on chromosome 1 and is partially responsible for familial adenomatous	
	polyposis. Stickler syndrome, Parkinsons, Gaucher disease and Usher syndrome are also	
	associated with chromosome 1. A breakpoint has been identified in 1q which disrupts the	
	DISC1 gene and is linked to schizophrenia. Aberrations in chromosome 1 are found in a variety	
	of cancers including head and neck cancer, malignant melanoma and multiple myeloma. The	
	C1orf141 gene product has been provisionally designated C1orf141 pending further	
	characterization.
