	Background: GBE1 is a 702 amino acid protein that is expressed at high levels in muscle and
	liver and is involved in glycogen biosynthesis. Existing as a monomer, GBE1 catalyzes the
	transfer of alpha-1,4-linked glucosyl units from the outer end of a glycogen chain to an alpha-
	1,6 position on a neighboring glycogen chain and, via this catalytic activity, plays an essential
	role in glycogen accumulation. Defects in the gene encoding GBE1 are the cause of glycogen
	storage disease type 4 (GSD4) and adult polyglucosan body disease (APBD), the first of which
	is a metabolic disorder that is associated with the accumulation of polysaccharides and is
	characterized by liver disease during childhood. Unlike GSD4, APBD is a late-onset disorder that
	affects the central and peripheral nervous systems and is characterized by cognitive
	impairment, pyramidal tetraparesis and peripheral neuropathy.
