| | Background: The temporal genetic hierarchy influencing normal limb development can | | |
| | deregulate and mediate mammalian developmental syndromes. In mice, the limb deformity (Id) | | |
| | locus influences normal limb development and gives rise to alternative mRNAs that can | | |
| | translate into a family of proteins known as formins. Formins play a crucial role in cytoskeletal | | |
| | reorganization by influencing Actin filament assembly. Formins co-localize with the actin | | |
| | cytoskeleton and can translocate into the cell cytosol and into the nucleus in an HGF-dependent | | |
| | manner. Vertebrate nuclear formins can control polarizing activity in limb buds through | | |
| | establishment of a Sonic hedgehog/FGF-4 feedback loop. Deficiency mutations at the | | |
| | mammalian ld locus lead to profound developmental defects in limb and kidney formation. The | | |
| | human Formin 1 and 2 genes map to chromosome 15q13.3 and 1q43, respectively. | | |
