Background: intracellular stimulation of guanylate cyclase (GC) by calcium, a key event in the
recovery of the dark state of rod photoreceptors after exposure to light, is mediated by
guanylate cyclase-activating protein (GCAP1). GCAPs are calcium-The binding proteins
belonging to the calmodulin superfamily. GCAP1 is a calcium-binding protein that stimulates
synthesis of c-GMP in photoreceptors. GCAP1 is present in rod and cone photoreceptor outer
segments where phototransduction occurs. In contrast to other calcium-binding proteins from
the calmodulin superfamily, the calcium-free form of GCAP1 stimulates the effector enzyme. By
molecular cloning of human and mouse GCAP cDNA, the known mammalian GCAPs are found
to be more than 90 % similar, consisting of 201 to 205 amino acids, and containing three
identically conserved calcium-binding sites. A related protein, GCAP2, is detectable only in the
retina and results from a gene duplication event.
