| Background: ADH6 (alcohol dehydrogenase 6), also known as ADH-5, is a 368 amino acid            |  |  |
| member of the class V zinc-containing alcohol dehydrogenase family. This family of enzymes      |  |  |
| functions to metabolize a wide variety of substrates such as retinol, hydroxysteroids, ethanol, |  |  |
| aliphatic alcohols and lipid peroxidation products. Localized to the cytoplasm and expressed in |  |  |
| the stomach and liver, ADH6 catalyzes the reversible oxidation of alcohols to their             |  |  |
| corresponding aldehydes or ketones and is able to bind two zinc ions as cofactors. ADH6         |  |  |
| contains a glucocorticoid response element upstream of its 5' UTR which is thought to be a      |  |  |
| steroid binding site, suggesting that expression of ADH6 may be under hormonal control.         |  |  |
| Multiple isoforms of ADH6 exist due to alternative splicing events.                             |  |  |
