	Background: The Golgi apparatus, which participates in glycosylation and transport of proteins	
	and lipids in the secretory pathway, consists of a series of stacked cisternae (flattened	
	membrane sacs). Interactions between the Golgi and microtubules are thought to be important	
	for the reorganization of the Golgi after it fragments during mitosis. This gene encodes one of	
	the golgins, a family of proteins localized to the Golgi. This protein is a coiled-coil membrane	
	protein that has been postulated to play a role in vesicle tethering and docking. Translocations	
	involving this gene and the ret proto-oncogene have been found in tumor tissues, the chimeric	
	sequences have been designated RET-II and PTC5. [provided by RefSeq, Feb 2010].
