	Apurinic-apyrimidinic endonuclease APLF, C2orf13, PNK and APTX like FHA protein, PNK and		
	APTX-like FHA domain-containing protein, RGD1565557, XIP1, XRCC1 interacting protein 1,		
	XRCC1-interacting protein 1.		
	Background: APLF is a 511 amino acid protein that contains one FHA doman and two		
	C2H2type zinc fingers. Localized to both the nucleus and the cytoplasm, APLF interacts with		
	XRCC1, XRCC4 and Ku-86 and, via these interactions, is involved in single-strand and double-		
	strand DNA break repair. APLF is subject to post-translational phosphorylation in response to		
	DNA breaks. The gene encoding APLF maps to human chromosome 2, which houses over		
	1,400 genes and comprises nearly 8 % of the human genome. Harlequin icthyosis, a rare and		
	morbid skin deformity, is associated with mutations in the ABCA12 gene, while the lipid		
	metabolic disorder sitosterolemia is associated with defects in the ABCG5 and ABCG8 genes.		
	Additionally, an extremely rare recessive genetic disorder, is caused by mutations in the ALMS1		
	gene, which maps to chromosome 2.		
Gene ID:	200558		
Pathways:	DNA Damage Repair
