|---------------------|---|
| | Drosophila, Transcription factor HES 2, HES2_HUMAN. |
| | Background: The Drosophila hairy and Enhancer of split genes encode basic helix-loop-helix |
| | (bHLH) transcriptional repressors that function in the Notch signaling pathway and control |
| | segmentation and neural development during embryogenesis. The mammalian homologues of |
| | Drosophila hairy and Enhancer of split are the HES gene family members, HES1-6, which also |
| | encode bHLH transcriptional repressors that regulate myogenesis and neurogenesis. The HES |
| | family members form a complex with TLE, the mammalian homologue of Groucho, and this |
| | interaction is mediated by the carboxy terminal WRPW motif of the HES proteins. The HES/TLE |
| | complex functions by directly binding to DNA, instead of interfering with activator proteins. |
| | Most HES family members, including HES1 and HES5, preferentially bind to the N box |
| | (CACNAG) as opposed to the E box (CANNTG). HES2 binds to both N and E box sites, while |
| | HES6 does not bind DNA. Rather, HES6 inhibits HES1 activity, thereby promoting transcription. HES1 and HES2 are expressed in a variety of adult and embryonic tissues. HES3 is expressed |
| | |
| | produced in brain as well as in the limb buds of developing embryos. |
