	Background: The exosome is a multi-subunit complex composed of several highly conserved	
	proteins, some of which are 3? to 5? exoribonucleases. The complex is involved in a variety of	
	cellular processes and is responsible for degrading unstable mRNAs that contain AU-rich (ARE	
	elements in their untranslated 3? region. EXOSC10, also known as PMSCL, PMSCL2, p2, p3, p4,	
	RRP6, Rrp6p, PM-Scl, or PM/Scl-100, is an 885 amino acid protein that contains one HRDC	
	domain and one 3?-5? enonuclease domain. Localized to both the cytoplasm and the nucleus,	
	EXOSC10 is part of the post-splicing exosome complex and is involved in mRNA surveillance, mRNA nuclear export and nonsense-mediated decay of mRNAs containing premature stop codons. against EXOSC10 have been found in patients with scleroderma and/or polymyositis	
	involved in the pathogenesis of these diseases. Two isoforms of EXOSC10 exist due to	
	alternative splicing events.
