	Background: Glucose and insulin are anabolic signals which upregulate the transcriptions of a
	series of lipogenic enzymes to convert excess carbohydrate into triglycerides for efficient
	energy storage. Acyl-coenzyme A:diacylglycerol acyltransferase, also known as DGAT1 and
	ARGP1, is a microsomal enzyme that assists in the synthesis of fatty acids into triglycerides.
	DGAT1 catalyzes the terminal and only committed step in triacylglycerol synthesis by using
	diacylglycerol (DAG) and fatty acyl CoA as substrates. DGAT1 plays a fundamental role in the
	metabolism of cellular diacylglycerol and is important in higher eukaryotes for physiologic
	processes involving triacylglycerol metabolism, such as intestinal fat absorption, lipoprotein
	assembly, adipose tissue form-ation and lactation. DGAT2, which has no homology to DGAT1,
	differs from DGAT1 in that its activity has been shown to be inhibited by MgCl in an in vitro
	assay. DGAT2 is expressed primarily in liver and white adipose tissue, which suggests that it
	plays an important role in mammalian triglyceride metabolism.
