	Background: Pokemon, the POK erythroid myeloid ontogenic factor, not only regulates the
	expression of many genes, but also plays an important role in cell tumorigenesis. To investigate
	the molecular mechanism regulating expression of the Pokemon gene in humans, its 5'-
	upstream region was cloned and analyzed. Transient analysis revealed that the Pokemon
	promoter is constitutive. Deletion analysis and a DNA decoy assay indicated that the NEG-U
	and NEG-D elements were involved in negative regulation of the Pokemon promoter, whereas
	the POS-D element was mainly responsible for its strong activity. Electrophoretic mobility shift
	assays suggested that the NEG-U, NEG-D and POS-D elements were specifically bound by the
	nuclear extract from A549 cells in vitro. Mutation analysis demonstrated that cooperation of the
	NEG-U and NEG-D elements led to negative regulation of the Pokemon promoter. Moreover, the
	NEG-U and NEG-D elements needed to be an appropriate distance apart in the Pokemon
	promoter in order to cooperate. Taken together, our results elucidate the mechanism underlying
	the regulation of Pokemon gene transcription, and also define a novel regulatory sequence that
	may be used to decrease expression of the Pokemon gene in cancer gene therapy.
