Background:	Synonyms: SCIDA, SNM1C, A-SCID, RS-SCID, DCLREC1C, Protein artemis, DNA cross-link repair
	1C protein, Protein A-SCID, SNM1 homolog C, hSNM1C, SNM1-like protein, DCLRE1C, ARTEMIS ASCID
	Background: Required for V(D)J recombination, the process by which exons encoding the
	antigen-binding domains of immunoglobulins and T-cell receptor proteins are assembled from
	individual V, (D), and J gene segments. $V(D)J$ recombination is initiated by the lymphoid specific
	RAG endonuclease complex, which generates site specific DNA double strand breaks (DSBs).
	These DSBs present two types of DNA end structures: hairpin sealed coding ends and
	phosphorylated blunt signal ends. These ends are independently repaired by the non
	homologous end joining (NHEJ) pathway to form coding and signal joints respectively. This
	protein exhibits single-strand specific 5'-3' exonuclease activity in isolation and acquires
	endonucleolytic activity on 5' and 3' hairpins and overhangs when in a complex with PRKDC.
	The latter activity is required specifically for the resolution of closed hairpins prior to the
	formation of the coding joint. May also be required for the repair of complex DSBs induced by
	ionizing radiation, which require substantial end-processing prior to religation by NHEJ.
