	Background: The exosome is a multi-subunit complex composed of several highly conserved
	proteins, some of which are 3? to 5? exoribonucleases. The complex is involved in a variety of
	cellular processes and is responsible for degrading unstable mRNAs that contain AU-rich (ARE
	elements in their untranslated 3? region. EXOSC10, also known as PMSCL, PMSCL2, p2, p3, p4,
	RRP6, Rrp6p, PM-Scl, or PM/Scl-100, is an 885 amino acid protein that contains one HRDC
	domain and one 3?-5? enonuclease domain. Localized to both the cytoplasm and the nucleus,
	EXOSC10 is part of the post-splicing exosome complex and is involved in mRNA surveillance,
	mRNA nuclear export and nonsense-mediated decay of mRNAs containing premature stop
	codons. against EXOSC10 have been found in patients with scleroderma and/or polymyositis
	(chronic diseases of the skin and muscle, respectively), suggesting that EXOSC10 may be
	involved in the pathogenesis of these diseases. Two isoforms of EXOSC10 exist due to
	alternative splicing events.
