	Background: KNDC1 is a 1,749 amino acid protein that contains two KIND domains and an N-		
	terminal Ras-GEF domain. Expressed in the cerebral cortex, KNDC1 is a likely guanine		
	nucleotide exchange factor (GEF). Existing as six alternatively spliced isoforms, the gene encoding KNDC1 maps to human chromosome 10q26.3 and mouse chromosome 7 F4. Spanning nearly 135 million base pairs, chromosome 10 makes up approximately 4.5 % of tota DNA in cells and encodes nearly 1,200 genes. Several protein-coding genes, including those		
	that encode for chemokines, cadherins, excision repair proteins, early growth response factors		
	(Egrs) and fibroblast growth receptors (FGFRs), are located on chromosome 10. Defects in		
	some of the genes that map to chromosome 10 are associated with Charcot-Marie Tooth		
	disease, Jackson-Weiss syndrome, Usher syndrome, nonsyndromatic deafness, Wolman?s		
	syndrome, Cowden syndrome, multiple endocrine neoplasia type 2 and porphyria.
