ARL1_HUMAN.
Background: The ADP-ribosylation factor (ARF) protein family are structurally and functionally
conserved members of the Ras superfamily of regulatory GTP-binding proteins (13). ARFs
influence vesicle trafficking and signal transduction in eukaryotic cells (13). ARF-dependent
regulatory mechanisms include the coordination of spectrin interactions with golgi membranes
and the association of actin to the golgi via rho family-dependent G-protein localization (Rac,
CDC42) and WASP/Arp2/3 complexes (37). Additionally, ARFs play a central role in
maintenance of organelle integrity, assembly of coat proteins, and activation of phospholipase
D (57). The ARF proteins are categorized as class I (ARF1, ARF2,and ARF3), class II (ARF4 and
ARF5) and class III (ARF6), members of each class share a common gene organization (8,9).
The human ARF6 gene maps to chromosome 7q22.1, contains five exons and four introns, and
encodes a 175 amino acid protein (8,9).
