	Background: C9orf23 (chromosome 9 open reading frame 23) is a 163 amino acid protein that	
	belongs to the histone-like Alba family and is encoded by a gene that maps to human	
	chromosome 9p13.3. Chromosome 9 consists of about 145 million bases, represents 4 % of	
	the human genome and encodes nearly 900 genes. Thought to play a role in gender	
	determination, deletion of the distal portion of 9p can lead to development of male to female	
	sex reversal, the phenotype of a female with a male X,Y genotype. Hereditary hemorrhagic	
	telangiectasia, which is characterized by harmful vascular defects, is associated with the	
	chromosome 9 gene encoding endoglin protein, ENG. Familial dysautonomia is also associated	
	with chromosome 9 though through the gene IKBKAP. Notably, chromosome 9 encompasses	
	the largest interferon family gene cluster. Chromosome 9 is partnered with chromosome 22 in	
	the translocation leading to the aberrant production of BCR-ABL fusion protein often found in	
	leukemias.
