	Background: Ethanolamine kinase 2, also known as EKI2, ETNK2 or HMFT1716, is a 386 amino	
	acid protein that belongs to the choline/ethanolamine kinase family. Via the cytidine	
	diphosphate (CDP) ethanolamine pathway, Ethanolamine kinase 2 catalyses the initial step of	
	phosphatidylethanolamine (PtdEtn) biosynthesis. Ethanolamine kinase 2 is expressed in kidney	
	liver, testis, ovary and prostate, and is highly specific for ethanolamine phosphorylation.	
	Upregulated during testis development, Ethanolamine kinase 2 may play an essential role in	
	regulating placental hemostasis. Existing as three alternatively spliced isoforms, the gene	
	encoding Ethanolamine kinase 2 maps to human and mouse chromosome 1. Human	
	chromosome 1 spans 260 million base pairs, contains over 3,000 genes, comprises nearly 8 $\%$	
	of the human genome and houses a large number of disease-associated genes, including thos	
	that are involved in familial adenomatous polyposis, Stickler syndrome, Parkinson?s disease,	
	Gaucher disease, schizophrenia and Usher syndrome.
