	cerevisiae homolog like, Origin recognition complex, subunit 1 like yeast, PARC1, Replication		
	control protein 1.		
	Background: The initiation of DNA replication is a multi-step process that depends on the		
	formation of pre-replication complexes, which trigger initiation (1). Among the proteins required		
	for establishing these complexes are the origin recognition complex (ORC) proteins (1). ORC		
	proteins bind specifically to origins of replication where they serve as scaffold for the assembly		
	of additional initiation factors (1). Human ORC subunits 1-6 are expressed in the nucleus of		
	proliferating cells and tissues, such as the testis (2). ORC1 and ORC2 are both expressed at		
	equivalent concentrations throughout the cell cycle, however, only ORC2 remains stably bound		
	to chromatin (3,4). ORC4 and ORC6 are also expressed constantly throughout the cell cycle		
	(5,6). ORC2, ORC3, ORC4 and ORC5 form a core complex upon which ORC6 and ORC1		
	assemble (7,8). The formation of this core complex suggests that ORC proteins play a crucial		
	role in the G1-S transition in mammalian cells (8).
