| | Background: GFM2 is a mitochondrial translation elongation factor. Its role in the regulation of |
| | normal mitochondrial function and in different disease states attributed to mitochondrial |
| | dysfunction is not known. Eukaryotes contain two protein translational systems, one in the |
| | cytoplasm and one in the mitochondria. Mitochondrial translation is crucial for maintaining |
| | mitochondrial function and mutations in this system lead to a breakdown in the respiratory |
| | chain oxidative phosphorylation system and to impaired maintenance of mitochondrial DNA. |
