Background:	Receptor tyrosine kinases (RTKs) play a key role in the communication of cells with their
	microenvironment. These molecules are involved in the regulation of cell growth, differentiation,
	and metabolism. In several cases the biochemical mechanism by which RTKs transduce

	signals across the membrane has been shown to be ligand induced receptor oligomerization
	and subsequent intracellular phosphorylation. This autophosphorylation leads to
	phosphorylation of cytosolic targets as well as association with other molecules, which are
	involved in pleiotropic effects of signal transduction. RTKs have a tripartite structure with
	extracellular, transmembrane, and cytoplasmic regions. This gene encodes a member of a
	novel subclass of RTKs and contains a distinct extracellular region encompassing a factor VIII-
	like domain. Alternative splicing in the 5' UTR results in multiple transcript variants encoding the
	same protein.
