Background:	The protein encoded by this gene is a member of the basic helix-loop-helix leucine zipper
	(bHLHZ) family of transcription factors. It is able to form homodimers and heterodimers with
	other family members, which include Mad, Mxi1 and Myc. Myc is an oncoprotein implicated in
	cell proliferation, differentiation and apoptosis. The homodimers and heterodimers compete for

	a common DNA target site (the E box) and rearrangement among these dimer forms provides a
	complex system of transcriptional regulation. Mutations of this gene have been reported to be
	associated with hereditary pheochromocytoma. A pseudogene of this gene is located on the
	long arm of chromosome 7. Alternative splicing results in multiple transcript variants.
