Background:	This gene encodes a member of the E protein (class I) family of helix-loop-helix transcription factors. E proteins activate transcription by binding to regulatory E-box sequences on target genes as heterodimers or homodimers, and are inhibited by heterodimerization with inhibitor of
	DNA-binding (class IV) helix-loop-helix proteins. E proteins play a critical role in lymphopoiesis,

and the encoded protein is required for B and T lymphocyte development. Deletion of this gene		
or diminished activity of the encoded protein may play a role in lymphoid malignancies. This		
gene is also involved in several chromosomal translocations that are associated with lymphoid		
malignancies including pre-B-cell acute lymphoblastic leukemia (t(119), with PBX1), childhood		
leukemia (t(1919), with TFPT) and acute leukemia (t(1219), with ZNF384). Alternatively spliced		
transcript variants encoding multiple isoforms have been observed for this gene, and a		
pseudogene of this gene is located on the short arm of chromosome 9.
