a diverse set of functions, including the control of blood coagulation, complement activation,
programmed cell death and development. Serpins are secreted glycoproteins that contain a
stretch of peptide that mimics a true substrate for a corresponding serine protease. SerpinB11
(serpin peptidase inhibitor, clade B (ovalbumin), member 11), also known as EPIPIN or
SERPIN11, is a 392 amino acid cytoplasmic protein that belongs to the Ov-serpin subfamily and
serpin family. Like other members of the serpin family, SerpinB11 has been identified as a
noninhibitory intracellular protein. The gene encoding SerpinB11 maps to human chromosome
18, which houses over 300 protein-coding genes and contains nearly 76 million bases. There
are a variety of diseases associated with defects in chromosome 18-localized genes, some of
which include Trisomy 18 (also known as Edwards syndrome), Niemann-Pick disease,
hereditary hemorrhagic telangiectasia, erythropoietic protoporphyria and follicular lymphomas.
