multiple organs in the body and also functions as a neuropeptide affecting electrical activity of
neurons. Somatostatin acts to regulate numerous physiological processes by binding to and
activating specific receptors in target tissues. There are five somatostatin receptor subtypes
termed SSTR 1 to 5. They are G protein coupled receptors characterized by seven
transmembrane helices with an extracellular amino terminal domain and an intracellular
carboxy terminus. These receptors are activated by somatostatin secreted by nerve and
endocrine cells and function in the regulation of numerous physiological processes such as the
secretion of insulin, glucagon and growth hormone. The SSTRs also play a role in cell growth
induced by neuronal excitation in both the central and peripheral nervous system. Somatostatin
receptors have been implicated in numerous diseases ranging from Alzheimer's to cancers of
the gastrointestinal tract, breast, prostate, and pituitary.
