Background:	Synonyms: hUTF 1, hUTF1, Undferentiated embryonic cell transcription factor 1, UTF 1, UTF1,
	UTF1_HUMAN.
	Background: UTF1 is a 341 amino acid protein that localizes to the nucleus and is subject to
	post-translational phosphorylation. Associating with the TFIID complex via an interaction with
	the TATA box binding protein (TFIID), UTF1 binds to the N-terminal region of ATF-2 and, via this
	binding, acts as a transcriptional coactivator of ATF-2, thereby enhancing transcriptional
	activity. Human UTF1 shares 64 % homology with its mouse counterpart, suggesting a similar
	role between species. The gene encoding UTF1 maps to human chromosome 10, which
	houses over 1,200 genes and comprises nearly 4.5 % of the human genome. Defects in some
	of the genes that map to chromosome 10 are associated with Charcot-Marie Tooth disease,
	Jackson-Weiss syndrome, Usher syndrome, nonsyndromatic deafness, Wolman?s syndrome,
	Cowden syndrome, multiple endocrine neoplasia type 2 and porphyria.
