Background:	Synonyms: NERP-2, Nerve growth factor inducible, Neuroendocrine regulatory peptide-2,	
	Neurosecretory protein VGF, VGF, VGF_HUMAN.	
	Background: This gene is specifically expressed in a subpopulation of neuroendocrine cells, and	
	is upregulated by nerve growth factor. The structural organization of this gene is similar to that	
	of the rat gene, and both the translated and the untranslated regions show a high degree of	
	sequence similarity to the rat gene. The encoded secretory protein also shares similarities with	
	the secretogranin/chromogranin family, however, its exact function is not known. Nerve growth	
	factor (NGF) is a peptide that plays a key role in the differentiation and survival of neurons in the	
	peripheral nervous system (PNS) and the central nervous system (CNS). VGF is a peptide	
	synthesized and secreted by neurons and is upregulated by NGF in the PC12 cell line. VGF is	
	widely expressed in both the PNS and CNS, but is especially abundant in the adult	
	hypothalamus. VGF plays an essential role in how the brain regulates energy expenditure and	
	body weight. Its expression is rapidly induced by injury, the circadian clock, and neuronal	
	activity.
