Background:	Synonyms: Chromosome 1 open reading frame 163, FLJ12439, Hcp beta lactamase like protein
	C1orf163, Hypothetical protein LOC65260, SELR1_HUMAN.
	Background: Chromosome 1 is the largest human chromosome spanning about 260 million
	base pairs and making up 8 % of the human genome. There are about 3,000 genes on
	chromosome 1, and considering the great number of genes there are also a large number of
	diseases associated with chromosome 1. Notably, the rare aging disease Hutchinson-Gilford
	progeria is associated with the LMNA gene which encodes lamin A. When defective, the LMNA
	gene product can build up in the nucleus and cause characteristic nuclear blebs. The
	mechanism of rapidly enhanced aging is unclear and is a topic of continuing exploration. The
	MUTYH gene is located on chromosome 1 and is partially responsible for familial adenomatous
	polyposis. Stickler syndrome, Parkinsons, Gaucher disease and Usher syndrome are also
	associated with chromosome 1. A breakpoint has been identified in 1q which disrupts the
	DISC1 gene and is linked to schizophrenia. Aberrations in chromosome 1 are found in a variety
	of cancers including head and neck cancer, malignant melanoma and multiple myeloma. The
	C1orf163 gene product has been provisionally designated C1orf163 pending further
	characterization.
