	receptor like 1, FGRL1_HUMAN.
	Background: FGFRL1 is a member of the fibroblast growth factor receptor (FGFR) family, where
	amino acid sequence is highly conserved between members and throughout evolution. FGFR
	family members differ from one another in their ligand affinities and tissue distribution. A full-
	length representative protein would consist of an extracellular region, composed of three
	immunoglobulin-like domains, a single hydrophobic membrane-spanning segment and a
	cytoplasmic tyrosine kinase domain. The extracellular portion of the protein interacts with
	fibroblast growth factors, setting in motion a cascade of downstream signals, ultimately
	influencing mitogenesis and differentiation. A marked difference between FGFRL1 and the
	other family members is its lack of a cytoplasmic tyrosine kinase domain. The result is a
	transmembrane receptor that could interact with other family members and potentially inhibit
	signaling. Multiple alternatively spliced transcript variants encoding the same isoform have
	been found.
