Alternative Name:	HSP70/HSC70 (HSC70-4 Products)
Background:	HSP70 genes encode abundant heat-inducible 70- kDa HSPs (HSP70s). In most eukaryotes
	HSP70 genes exist as part of a multigene family. They are found in most cellular compartments
	of eukaryotes including nuclei, mitochondria, chloroplasts, the endoplasmic reticulum and the
	cytosol, as well as in bacteria. The genes show a high degree of conservation, having at least
	50 % identity (2). The N-terminal two thirds of HSP70s are more conserved than the C-terminal
	third. HSP70 binds ATP with high affinity and possesses a weak ATPase activity which can be
	stimulated by binding to unfolded proteins and synthetic peptides (3). When HSC70
	(constitutively expressed) present in mammalian cells was truncated, ATP binding activity was
	found to reside in an N-terminal fragment of 44 kDa which lacked peptide binding capacity.
	Polypeptide binding ability therefore resided within the C-terminal half (4). The structure of this
	ATP binding domain displays multiple features of nucleotide binding proteins (5). All HSP70s,
	regardless of location, bind proteins, particularly unfolded ones. The molecular chaperones of
	the HSP70 family recognize and bind to nascent polypeptide chains as well as partially folded
	intermediates of proteins preventing their aggregation and misfolding. The binding of ATP
	triggers a critical conformational change leading to the release of the bound substrate protein
	(6). The universal ability of HSP70s to undergo cycles of binding to and release from
	hydrophobic stretches of partially unfolded proteins determines their role in a great variety of
	vital intracellular functions such as protein synthesis, protein folding and oligomerization and
	protein transport. For more information visit our HSP70 Scientific Resource Guide at
