Target Details

Background:	Covalent modification of histones plays critical role in regulating chromatin structure and
	transcription. While most covalent histone modifications are reversible, only recently has it been
	established that methyl groups are subject to enzymatic removal from histones. A family of
	novel JmjC domain-containing histone demethylation (JHDM) enzymes have been identified
	that perform this specific function. Histone demethylation by JHDM proteins requires cofactors
	Fe(II) and alpha-ketoglutarate. Family members include JHDM1 (demethylating histone 3 at
	lysine 36), and JHDM2A as well as JMJD2CH3K9 (both of which demethylate histone 3 at
	lysine 9). Contributions of histone demethylase activity to tumor development, decreases in cell
	proliferation, and hormone-dependent transcriptional activation have been observed.
