## Target Details

Background:	ROR2 is a tyrosine-protein kinase receptor which may be involved in the early formation of the
	chondrocytes. It seems to be required for cartilage and growth plate development. This Type I
	membrane protein is expressed at high levels during early embryonic development. The
	expression levels drop strongly around day 16 and there are only very low levels in adult tissues.
	Defects in ROR2 are a cause of brachydactyly type B1 (BDB1). BDB1 is an autosomal dominant
	skeletal disorder characterized by hypoplasia/aplasia of distal phalanges and nails. In BDB1 the
	middle phalanges are short but in addition the terminal phalanges are rudimentary or absent.
	Both fingers and toes are affected. The thumbs and big toes are usually deformed. Defects in
	ROR2 are a cause of recessive Robinow syndrome (RRS). RRS is an autosomal disorder
	characterized by skeletal dysplasia with generalized limb bone shortening, segmental defects
	of the spine, brachydactyly and a dysmorphic facial appearance. The protein contains 1 frizzled
	(FZ) domain, 1 immunoglobulin-like C2-type domain, and 1 kringle domain.

#### Immunohistochemistry (Paraffin-embedded Sections)

**Image 1.** Formalin-fixed and paraffin-embedded human cancer tissue reacted with the primary antibody, which was peroxidase-conjugated to the secondary antibody, followed by DAB staining. This data demonstrates the use of this antibody for immunohistochemistry, clinical relevance has not been evaluated. BC = breast carcinoma, HC = hepatocarcinoma.
