	Background: The DAZ (Deleted in AZoospermia) gene family encodes potential RNA binding	
	proteins that are expressed in prenatal and postnatal germ cells of males and females. The	
	protein encoded by this gene is localized to the nucleus and cytoplasm of fetal germ cells and	
	to the cytoplasm of developing oocytes. In the testis, this protein is localized to the nucleus of	
	spermatogonia but relocates to the cytoplasm during meiosis where it persists in spermatids	
	and spermatozoa. Transposition and amplification of this autosomal gene during primate	
	evolution gave rise to the DAZ gene cluster on the Y chromosome. Mutations in this gene have	
	been linked to severe spermatogenic failure and infertility in males. Two transcript variants	
	encoding different isoforms have been found for this gene. [provided by RefSeq, Jun 2010].
