## Target Details

Background:	The Epithelial Sodium Channel (ENaC) is a membrane ion channel permeable to Na+ ions. It is
	located in the apical plasma membrane of epithelia in the kidneys, lung, colon, and other tissues
	where it plays a role in trans epithelial Na+-ion transport (1). Specifically Na+ transport via ENaC
	occurs across many epithelial surfaces, and plays a key role in regulating salt and water
	absorption (2). ENaCs are composed of three structurally related subunits that form a
	tetrameric channel, alpha, beta, and gamma. The expression of its alpha and beta subunits is
	enhanced as keratinocytes differentiate (3, 4). The beta and gamma-ENaC subunits are
	essential for edema fluid to exert its maximal effect on net fluid absorption by distal lung
	epithelia(5). And it has been concluded that the subunits are differentially expressed in the
	retina of mice with ocular hypertension, therefore the up-regulation of alpha-ENaC proteins
	could serve as a protection mechanism against elevated intraocular pressure (6).
