	Background: Clathrin-mediated endocytosis is the pathway by which many receptors for
	nutrients and hormones are internalized to be recycled or down-regulated. During formation of
	clathrin coated membranes, clathrin co-assembles with heterotetrameric molecules known as
	assembly polypeptides (APs) or adaptors which form a layer of protein coat between the
	clathrin lattice and the membrane. There are two characterized adaptors AP1 and AP2. AP1 is
	associated with clathrin coated vesicles at the trans-Golgi network and AP2 is associated with
	the endocytic clathrin coated vesicles at the plasma membrane and has been shown to
	specifically interact with Shc and EGF receptor. AP2 is composed of four subunits, two
	separate 100 kDa gene products with similar domain structures (alpha and beta adaptin) and
	50 and 17 kDa subunit. There are two alpha-adaptin genes, alpha A and alpha C which have a
	tissue specific pattern of expression.
