|                     | Background: Clathrin-mediated endocytosis is the pathway by which many receptors for               |
|                     | nutrients and hormones are internalized to be recycled or down-regulated. During formation of      |
|                     | clathrin coated membranes, clathrin co-assembles with heterotetrameric molecules known as          |
|                     | assembly polypeptides (APs) or adaptors which form a layer of protein coat between the             |
|                     | clathrin lattice and the membrane. There are two characterized adaptors AP1 and AP2. AP1 is        |
|                     | associated with clathrin coated vesicles at the trans-Golgi network and AP2 is associated with     |
|                     | the endocytic clathrin coated vesicles at the plasma membrane and has been shown to                |
|                     | specifically interact with Shc and EGF receptor. AP2 is composed of four subunits, two             |
|                     | separate 100 kDa gene products with similar domain structures (alpha and beta adaptin) and         |
|                     | 50 and 17 kDa subunit. There are two alpha-adaptin genes, alpha A and alpha C which have a         |
|                     | tissue specific pattern of expression.   |
