| | Background: This endogenous retroviral envelope protein has retained its original fusogenic | | |
|---------------------|--|--|--|
| | properties and participates in trophoblast fusion and the formation of a syncytium during | | |
| | placenta morphogenesis. May induce fusion through binding of SLC1A4 and SLC1A5 | | |
| | (PubMed:10708449, PubMed:12050356, PubMed:23492904). Endogenous envelope proteins | | |
| | may have kept, lost or modified their original function during evolution. Retroviral envelope | | |
| | proteins mediate receptor recognition and membrane fusion during early infection. The surface | | |
| | protein (SU) mediates receptor recognition, while the transmembrane protein (TM) acts as a | | |
| | class I viral fusion protein. The protein may have at least 3 conformational states: pre-fusion | | |
| | native state, pre-hairpin intermediate state, and post-fusion hairpin state. During viral and target | | |
| | cell membrane fusion, the coiled coil regions (heptad repeats) assume a trimer-of-hairpins | | |
| | structure, positioning the fusion peptide in close proximity to the C-terminal region of the | | |
| | ectodomain. The formation of this structure appears to drive apposition and subsequent fusion | | |
| | of membranes. | | |
